SI649-F21 -> Altair II

Overview

We will continue working with the dataset from the article "The Dollar-And-Cents Case Against Hollywood's Exclusion of Women" (https://fivethirtyeight.com/features/the-dollar-and-cents-case-against-hollywoods-exclusion-of-women/). We'll focus on **transformation** and build the following charts:

1. Line chart within a range
2. Heatmap with additional annotations
3. Bar chart with additional annotations
4. Bar chart with fold

After building these charts, you will make a website with these charts using streamlit.

Lab Instructions

- For this lab, please write Altair code to answer the questions. In many situations you could also solve the problem using Pandas. However, we want code that can be deployed without using Python so it's better practice to just do as much as we can in Altair. You can complete the entire lab without writing any pandas transformation.
- It's fine if your visualization looks slightly different from the example (e.g., getting 1.1 instead of 1.0, use orange instead of red)
- Save, rename, and submit the ipynb file (use your username in the name).
- Run every cell (do Runtime -> Restart and run all to make sure you have a clean working version), print to pdf, rename, submit the pdf file.
- For each visualization, we will ask you to write down a "Grammar of Graphics" plan first (basically a description of what you'll code).
- If you end up stuck, show us your work by including links (URLs) that you have searched for. You'll get partial credit for showing your work in progress.
- There are many bonus point opportunities in this lab.

```
In [1]:  # imports we will use
         import altair as alt
         import pandas as pd
         datasetURL="https://raw.githubusercontent.com/eytanadar/si649public/master/lab5/assets/hw/movie_after
         movies_test=pd.read_csv(datasetURL, encoding="latin-1")
```

Here's the processed Bechdel test dataset.

```
In [2]: movies_test
```

1615 rows × 14 columns

Visualization 1: Line chart within a range
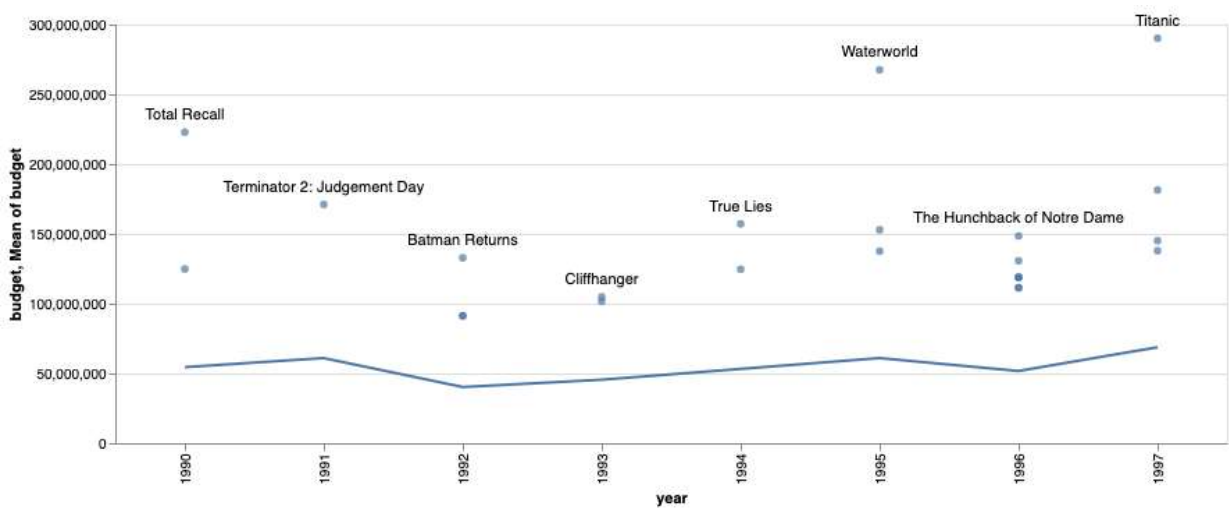

Description of the visualization:

We want to see a visualization of movies that were significantly above budget relative to the mean. We'd like to know the name of the top movie that year but also to have a sense of how many other outliers (we'll defined those as at least 2x the mean budget) were produced that year.

- Plot a line chart using year and average budget for movies between 1990 and 1997.
- Plot dots to represent movies with budgets that are at least 2 times bigger than the mean budget of that year. (e.g., if the mean budget of 1990 is 50M, plot movies made in 1990 whose budgets are at least 100M)
- For each year, annotate the title of the movie with the highest budget of that year.

Visualization 1 Plan:

TODO: edit this cell to write your visualization plan. You can write in altair syntax, in full sentence, or in bullet points, whichever way that helps you to plan your chart.

line chart

- Describe the encoding rules:

  > x: X: year: O y: Y: mean_budget: Q

- Describe the transformations:

  > I'll set a filter transformation on year which should starts from 1990 to 1997
  > I'll create a quantitative field "mean_budget" indicates the mean budget group by year through transform_joinaggregate I'll create a quantitative field "max_budget" indicates the max budget group by year through transform_joinaggregate I'll create a nominal field "high_budget" indicates whether the budget is 2 times bigger than the mean_budget through transfrom_calculate

dot chart

- Describe the encoding rules:

  > x: X: year: O y: Y: budget: Q

- Describe the transformations:

  > I'll apply all transformations used on line chart I'll use a filter transformation where high_budget is True

text annotation

- Describe the encoding rules:

  > text: Text: title: N

- Describe the transformations:

 > I'll use a filter transformation where budget=max_budget

Replicate Vis 1

Hint:

- Line chart is the simplest one, you can start from there.
- Think about the difference between transform_aggregate and transform_joinaggregate

```
In [3]:  #TODO: Replicate visualization 1
         base = alt.Chart(movies_test).transform_filter(
             "datum.year>=1990 & datum.year <= 1997"
         ).transform_joinaggregate(
             mean_budget = "mean(budget):Q",
             max_budget = "max(budget):Q",
             groupby=["year"]
         ).transform_calculate(
             high_budget="datum.budget >= 2 * datum.mean_budget ? 'High' : 'Low'"
         ).encode(x=alt.X("year:O"))
         line = base.mark_line().encode(y=alt.Y("mean_budget:Q"))
         dot = line.transform_filter(
             alt.FieldOneOfPredicate(field="high_budget", oneOf=["High"])
         ).mark_point(filled=True).encode(y=alt.Y("budget:Q"))
         text = dot.mark_text(align="center", dy=-10).transform_filter(
             "datum.budget == datum.max_budget"
         ).encode(
             text=alt.Text("title:N")
         )
         (dot + line + text).properties(height=300, width=750)
```

Out[3]:
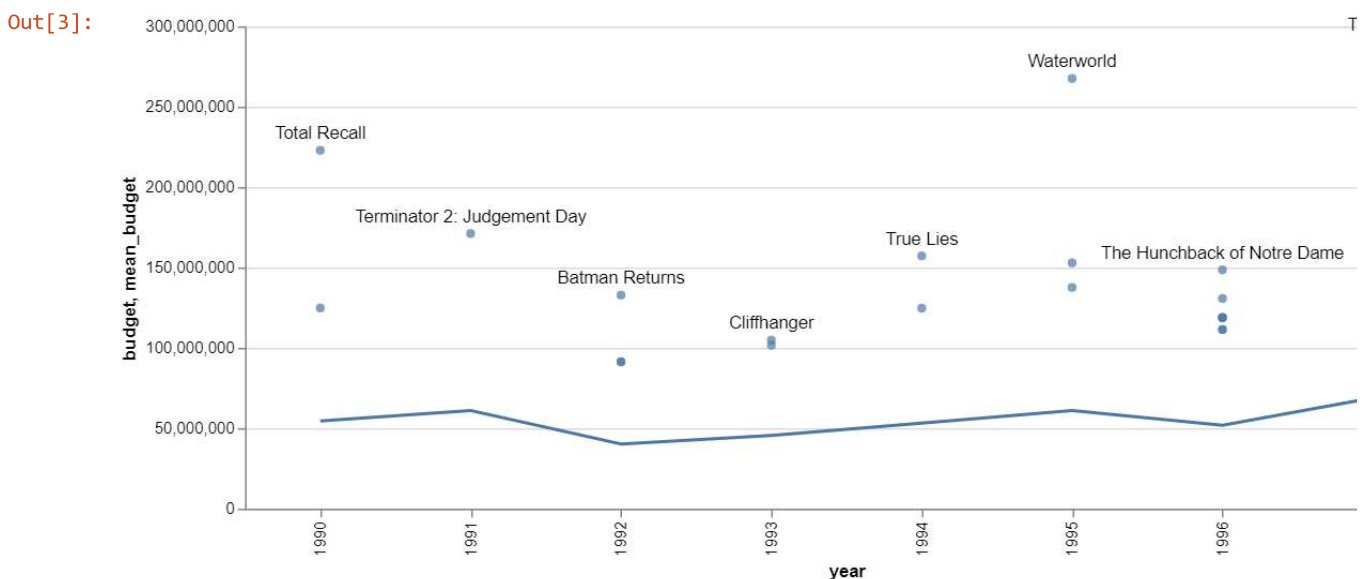

Visualization 2: heatmap with additional annotations
Description of this visualization:

We want to produce a heatmap contrasting different types of bechdel test results to the IMDB scores of those movies. Each cell in the heatmap will tell us how many movies (not normalized here, we want raw count) are in that category. The author of the article wants to point out some property of the really well-regarded movies so wants those highlighted.

- Plot a heatmap with rating (binned) and test result. Encode the count of movies as color. Remove the category "dubious".
- For each cell, add text to indicate the count of movies.
- If a test_result category has at least one movie whose rating is higher than 9, highlight that entire category in red. You can highlight by adding a layer of heatmap that is not filled.

Visualization2 Plan:

TODO: edit this cell to write your visualization plan. You can write in altair syntax, in full sentence, or in bullet points, whichever way that helps you to plan your chart.

heatmap

- Describe the encoding rules:

  > x: X: rating: Q
  > y: Y: test_result: N color: Color: count: Q

- Describe the transformations:

  > I'll use transform filter where the test_result shouldn't be dubious

text annotation

- Describe the encoding rules:

  > x: X: rating: Q
  > y: Y: test_result: N text: Text: count: Q

- Describe the transformations:

  > TODO: your answer here

highlight

- Describe the encoding rules:

  > x: X: rating: Q
  > y: Y: test_result: N

- Describe the transformations:

  > I'll createa field max_rating by getting the max rating of each test_result through transform joinaggregate I'll use a transform filter where the max_rating field should greater than 9

Replicate Vis 2

Hint:

- When you pass the heatmap to your text chart, you are passing all of the heatmap's encoding settings as well, which include the color setting.
- How do you translate "at least one movie with rating > 9 " into code?

```
In [4]:  #TODO: Replicate vis 2
         base = alt.Chart(movies_test).transform_filter(
             alt.FieldOneOfPredicate(field="test_result", oneOf=['Passes Bechdel Test', 'Fewer than two women'
         )
         heat = base.mark_rect().encode(
             x=alt.X("rating:Q", bin=True),
             y=alt.Y("test_result:N"),
             color=alt.Color("count():Q")
         )
         text = base.mark_text().encode(
             x=alt.X("rating:Q", bin=True),
             y=alt.Y("test_result:N"),
             text=alt.Text("count():Q")
         )
         high_light = base.transform_joinaggregate(
             max_rating="max(rating)",
             groupby=["test_result"]
         ).transform_filter(
             "datum.max_rating>=9"
         ).mark_rect(color="red", filled=False).encode(
             x=alt.X("rating:Q", bin=True),
             y=alt.Y("test_result:N")
         )
         heat + text + high_light
```

Out[4]:

Visualization 3: Bar chart with additional annotations
Description of this visualization: We want to contrast the domestic and international gross based on bedchel test passing category. We also want an example movie for each category so we're going to pick the 10th most popular one.

- Plot a bar chart for movies made in US and Canada, using the test result and mean of domestic gross.
- For test result category (i.e., each bar), find out the movie whose domestic gross ranks as the 10th lowest (sort by ascending order, the rank = 10). Annotate the title of this movie as text.
- Encode the mean domestic gross as color.
- BONUS: Align the text annotations with your bars.
- BONUS: Plot a similar bar chart for movies made internationally using the international gross. Concatenate the international and domestic charts charts. Make sure they share the same x axis but have independent color scales.

Visualization3 Plan:

TODO: edit this cell to write your visualization plan. You can write in altair syntax, in full sentence, or in bullet points, whichever way that helps you to plan your chart.

bar chart

- Describe the encoding rules:
- x: X: mean(demo_gross): Quantitative
- y: Y: test_result: Nominal
- Describe the transformations:
- I'll use a transform filter where country_binary is U.S. and Canada

text annotation

- Describe the encoding rules:
- text: Text: Title: Nominal
- y: Y: test_result: Nominal
- Describe the transformations::
- I'll apply a transform_window get the ascending rank of dom_gross grouped by the test result to get another field "gross_rank"
- I'll add a transform filter where the "gross_rank" should equals to 10

Replicate Vis 3

Hint:

- You want to generate the rank using a transformation method that we have covered in class.
- It's fine if text annotations don't align perfectly with your bars.

```
In [186]: #TODO: Replicate Vis 3
          dom = alt.Chart(movies_test).transform_filter(
              alt.FieldOneOfPredicate("country_binary", oneOf=["U.S. and Canada"]),
          ).encode(
              y=alt.Y("test_result:N")
          ).mark_bar(color="blue").encode(
              x=alt.X("mean(dom_gross)"),
              color=alt.Color("mean(dom_gross)")
          )
          text_dom = alt.Chart(movies_test).transform_filter(
              alt.FieldOneOfPredicate("country_binary", oneOf=["U.S. and Canada"])
          ).transform_window(
              sort=[alt.SortField("dom_gross", order="ascending")],
              gross_rank="rank(dom_gross)",
              groupby=["test_result"]
          ).transform_filter("datum.gross_rank==10").mark_text(align="left", x=10).encode(
              y=alt.Y("test_result:N"),
              text=alt.Text("title:N"),
          )
          dom += text_dom

          inter = alt.Chart(movies_test).transform_filter(
              alt.FieldOneOfPredicate("country_binary", oneOf=["International"]),
          ).encode(
              y=alt.Y("test_result:N")
          ).mark_bar(color="blue").encode(
              x=alt.X("mean(int_gross)"),
              color=alt.Color("mean(int_gross)", scale=alt.Scale(range=["white", "darkred"]))
          )
          text_int = alt.Chart(movies_test).transform_filter(
              alt.FieldOneOfPredicate("country_binary", oneOf=["International"])
          ).transform_window(
              sort=[alt.SortField("int_gross", order="ascending")],
              int_rank="rank(int_gross)",
              groupby=["test_result"]
          ).transform_filter("datum.int_rank==10").mark_text(align="left", x=10, color="white").encode(
              y=alt.Y("test_result:N"),
              text=alt.Text("title:N"),
          )
          inter += text_int
          (dom & inter).resolve_scale(x="shared", color="independent")
```

Out[186]:
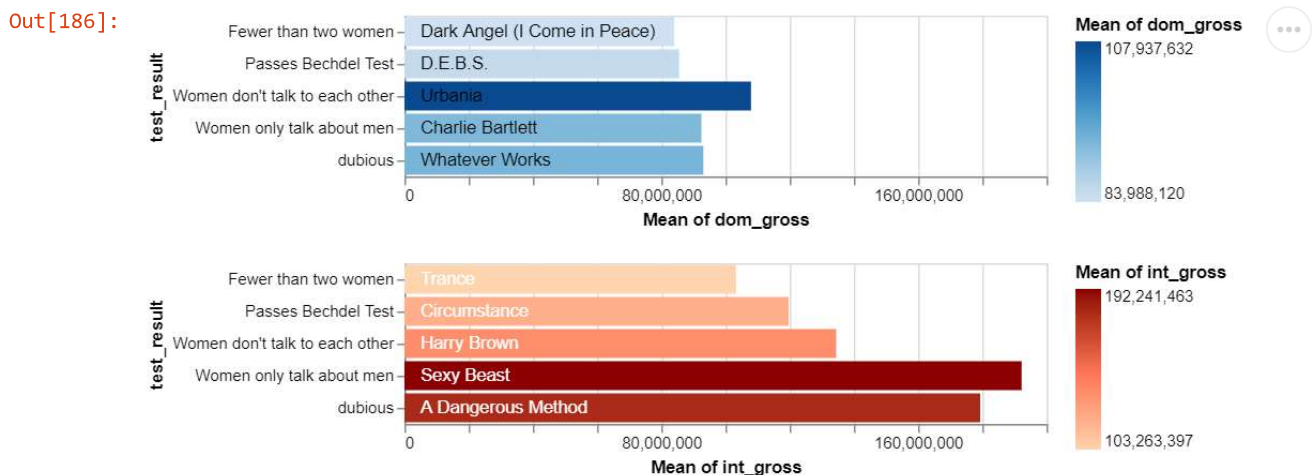

Visualization 4: Bar chart

Description of this visualization:

- Plot a bar chart that enables the comparison between mean budget and mean international gross across the whole dataset.
- Two bars should be colored differently

Visualization4 Plan:

TODO: edit this cell to write your visualization plan. You can write in altair syntax, in full sentence, or in bullet points, whichever way that helps you to plan your chart.

- What kind of transformation do I need to plot this bar chart?
- I'll use a transform_fold to label budget and int_gross in finance column, and call their corresponding value as dollars
- What kind of encoding do I want to use??
- x: X: mean(dollars): Quantitative
- y: Y: finance: Nominal
- color: Color: finance: Nominal

## Replicate Vis 4

Hint:

- Do I need a long form or wide form data? Which type of data do I have? What transformation can I use?

```
In [195]:  #TODO: replicate vis 4
           alt.Chart(movies_test).transform_fold(
               ["budget", "int_gross"],
               as_=["finance", "dollars"]
           ).mark_bar().encode(
               x=alt.X("mean(dollars):Q"),
               y=alt.Y("finance:N"),
               color=alt.Y("finance:N")
           )
```

Out[195]:
Export Instruction

For this lab, we want you to build a website with streamlit. You finished website will have a select widget on the sidebar. Depending on what the user selects, the website will display the corresponding visualization.
To make this website, you will need to

1. Go over the material we provided on streamlit.
2. Make a new python script for streamlit. Make sure you import the streamlit package.
3. Create a title
4. Create a selectbox on the sidebar, with 4 options (e.g., vis1, vis2, vis3, and vis4).
5. Copy-paste the code used to generate visualizations. Make sure each chart is saved to a variable.
6. Connect charts with the selected option by adding an if-else-then statement.

This is the end of lab 5.

Please run all cells in your notebook, and

1. save to PDF (File->Print->Save PDF -> landscape, shrink to 80%)
2. save to ipynb (File -> Download .ipynb)
3. save the python file that contains your streamlit app.

Rename files with your uniqname: e.g. uniqname.pdf/ uniqname.ipynb/uniquename.py

Upload all three files to canvas.
